Subject: Windows 95 Group Policy Support

CONFIDENTIAL

We are trying to get group policies to work with our client. However, there is no documented method for our client to pass group information to POEDIT.EXE. When we looked at the GROUPOPOL.INF and GROUPOPOL.REG files, it became obvious that there is some interface that we are not aware of, which has not been documented.

The GROUPOPOL.REG file sets a value under the Network Provider key:

```
{HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\NWP32\NetworkProvider}
```

the value is:

```
"GroupFcn"="GROUPOPOL.DLL,NWGetUserGroups"
```

I assume this tells GROUPOPOL.DLL which entry point to call to get the group and user information.

How can we implement this? Where is it documented? Is this function supposed to be implemented in the Network Provider? It's not documented anywhere in the Network Provider spec.

Any documentation you could give us on the interface between POEDIT.EXE, GROUPOPOL.DLL, and the Network Provider DLL would be appreciated.

Thanks,
